

FIRST MILNOR COHOMOLOGY OF HYPERPLANE ARRANGEMENTS

NERO BUDUR, ALEXANDRU DIMCA, AND MORIHIKO SAITO

Dedicated to Professor Anatoly Libgober

ABSTRACT. We show a combinatorial formula for a lower bound of the dimension of the non-unipotent monodromy part of the first Milnor cohomology of a hyperplane arrangement satisfying some combinatorial conditions. This gives exactly its dimension if a stronger combinatorial condition is satisfied. We also prove a non-combinatorial formula for the dimension of the non-unipotent part of the first Milnor cohomology, which apparently depends on the position of the singular points. The latter generalizes a formula previously obtained by the second named author.

Introduction

Let D be a hyperplane arrangement in $X = \mathbf{C}^n$. We assume D is reduced and central, i.e. D is defined by a reduced homogeneous polynomial f . We also assume that D does not come from an arrangement in $\mathbf{C}^{n-1}$, i.e. f cannot be expressed as a polynomial of $n-1$ variables. Set $F_f = f^{-1}(1)$. This is the Milnor fiber of f . Let T be the Milnor monodromy on $H^j(F_f, \mathbf{Q})$. We have the monodromy decomposition

$$H^j(F_f, \mathbf{C}) = \bigoplus_{\lambda} H^j(F_f, \mathbf{C})_{\lambda},$$

with $H^j(F_f, \mathbf{C})_{\lambda}$ the λ -eigenspace. Let $d = \deg D$. Set $Z := \mathbf{P}(D) \subset Y := \mathbf{P}^{n-1}$ and $U := \mathbf{P}^{n-1} \setminus Z$. It is well-known (see e.g. [CS], [Di1]) that $H^j(F_f, \mathbf{C})_{\lambda} = 0$ if $\lambda^d \neq 1$, and there are local systems $L^{(k)}$ of rank 1 on U for $k = 0, \dots, d-1$ such that

$$H^j(F_f, \mathbf{C})_{\lambda} = H^j(U, L^{(k)}) \quad \text{for } \lambda = \exp(2\pi i k/d),$$

and the monodromy around any irreducible component of Z is the multiplication by $\exp(-2\pi i k/d)$. In particular, $L^{(0)} = \mathbf{C}_U$ so that $H^j(F_f, \mathbf{C})_1 = H^j(U, \mathbf{C})$. It has been conjectured that the $H^j(F_f, \mathbf{C})_{\lambda}$ are combinatorial invariants. By [OS], the cohomology $H^{\bullet}(U, \mathbf{C}) = H^{\bullet}(F_f, \mathbf{C})_1$ is combinatorially described.

Let $Y' = \mathbf{P}^2$ be a sufficiently general linear subspace of dimension 2 in $Y = \mathbf{P}^{n-1}$. By the generalized weak Lefschetz theorem for perverse sheaves (i.e. Artin's

theorem in [BBD]), we have an isomorphism

$$(0.1) \quad H^1(U, L^{(k)}) = H^1(Y' \cap U, L^{(k)}|_{Y' \cap U}).$$

Thus we may assume $n = 3$ since we are interested in $b_1(F_f)_\lambda := \dim H^1(F_f)_\lambda$.

Set $\Sigma = \{y \in Z \mid \text{mult}_y Z \geq 3\}$. Let $Z_1, \dots, Z_d$ be the irreducible components of Z . For $y \in \Sigma$ and $I \subset \{1, \dots, d\}$, set $m_y := \text{mult}_y Z = \#\{i \mid y \in Z_i\}$, and

$$m_{I,y} := \#\{i \in I \mid y \in Z_i\}, \quad \alpha_{I,y} := \frac{|I|}{d} m_y - m_{I,y}.$$

The following would be known to specialists.

Proposition 1. *Let $\lambda = \exp(2\pi i k/d)$ with $k \in \mathbf{Z} \cap [1, d/2]$. Then $b_1(F_f, \mathbf{C})_\lambda$ is described combinatorially by using the Aomoto complex as in (1.2) with ω given in (1.2.3), if there is $I \subset \{1, \dots, d\}$ such that $|I| = k$ and*

$$(0.2) \quad \text{either } \alpha_{I,y} \notin \mathbf{Z}_{>0} \ (\forall y \in \Sigma) \quad \text{or} \quad \alpha_{I,y} \notin \mathbf{Z}_{<0} \ (\forall y \in \Sigma).$$

In case the second condition of (0.2) is satisfied, we actually consider $k' := d - k$ and the complement I^c of I instead of k and I by using the complex conjugation on the Milnor cohomology so that $\alpha_{I,y}$ is replaced by $-\alpha_{I,y}$. In fact, this is the reason for which we assume $k \leq d/2$; the case $k > d/2$ is treated in the second case of (0.2). The proof of Proposition 1 follows from a theorem of H. Esnault, V. Schechtman and E. Viehweg [ESV] about Aomoto's conjecture (here [STV] is not needed since $n = 3$) together with a combinatorial description of the cohomology of the complement due to P. Orlik and L. Solomon [OS], see (1.2) below. Proposition 1 was essentially used in a calculation of examples in [Sa2] although the combinatorial description of $H^\bullet(U)$ in [OS] was not mentioned there. It is possible to give a combinatorial description of $H^\bullet(U)$ in a more geometric way using the theory of perverse sheaves [BBD], see also [BS].

If $k = d/3 \in \mathbf{N}$ and $m_y = 3 \ (\forall y \in \Sigma)$, then condition (0.2) in Proposition 1 becomes

$$(0.3) \quad \text{either } m_{I,y} \geq 1 \ (\forall y \in \Sigma) \quad \text{or} \quad m_{I,y} \leq 1 \ (\forall y \in \Sigma).$$

Note that the first condition of (0.3) is equivalent to that Σ is covered by $\bigcup_{i \in I} Z_i$. There are examples where neither condition of (0.3) is satisfied, see Example (3.1)(iii) below.

Returning to the general situation (with $n = 3$), it is well-known that $b_1(F_f)_\lambda = 0$ unless there is $y \in \Sigma$ with $\lambda^{m_y} = 1$, see Remark (3.4)(i) below. (In this case we have actually a stronger assertion that $b_1(F_f)_\lambda = 0$ unless each Z_i contains $y \in \Sigma$ with $\lambda^{m_y} = 1$, see Remark (3.4)(ii) below.) Using Proposition 1, we can show the following.

Theorem 1. *Assume $n = 3$. Let $m, r \in \mathbf{Z} \cap [3, d-1]$ with $d/m \in \mathbf{Z}$. Assume there is a map $\phi : \{1, \dots, d\} \rightarrow \{1, \dots, r\}$. Set $I_j = \phi^{-1}(j)$, $m_{j,y} = m_{I_j,y}$, $\Sigma_{\langle d \rangle} = \Sigma \setminus Z_d$,*

$$\Sigma^\phi = \{y \in \Sigma \mid \{y\} = Z_i \cap Z_{i'} \text{ with } \phi(i) \neq \phi(i')\}, \quad \Sigma_{\langle d \rangle}^\phi = \Sigma^\phi \cap \Sigma_{\langle d \rangle}.$$

(i) *Assume λ is an m -th root of unity and the following conditions are satisfied.*

$$(0.4) \quad m_{j,y} > 0 \ (\forall y \in \Sigma_{\langle d \rangle}^\phi), \text{ and the } m_{j,y}/m_{j',y} \text{ are independent of } y \in \Sigma_{\langle d \rangle}^\phi.$$

$$(0.5) \quad \exists j_0 \text{ s.t. } |I_{j_0}| = d/m, \quad m_{j_0, y} = \frac{1}{m} \sum_{j=1}^r m_{j, y} \quad (\forall y \in \Sigma_{\langle d \rangle}^\phi).$$

Then $b_1(F_f)_\lambda \geq r - 2$.

(ii) Assume λ is a primitive m -th root of unity and the following condition is satisfied.

$$(0.6) \quad m_{j, y} = 1 \quad (\forall y \in \Sigma^\phi), \quad m = r, \text{ and } (0.2) \text{ is satisfied for some } I_{j_0}.$$

Then $b_1(F_f)_\lambda = m - 2$.

If the first condition of (0.6) is satisfied, i.e. if $m_{j, y} = 1$ ($\forall y \in \Sigma^\phi$), then we have $|\Sigma^\phi| = |I_j| |I_{j'}|$ for any $j \neq j'$ so that $|I_j| = d/r$ for any j , and conditions (0.4-5) with $m = r$ are satisfied. Hence Z is an $(m, d/m)$ -net in the sense of [FY]. By the Nullstellensatz there is a pencil such that $\bigcup_{\phi(i)=j} Z_i$ is a special fiber of the pencil for any j , see [Yu2], Lemma 3.1. This implies another proof of Theorem 1 (i) in this case, see [DP], Th. 3.1 (i) (or Remark (3.3)(i) below). Note that we have $m \leq 4$ in this case by [St2], [Yu3]. For the moment any known examples are essentially of this type. For $m = 3$, there are lots of examples where (0.6) is satisfied, see [Yu2] (and Remark (3.2)(ii) below). For $m = 4$, however, only one example is known, see [FY] (and Remark (3.3)(iii) below). Note that the last example implies a rather artificial example where conditions (0.4-5) are satisfied for $m = 4$ and $r = 3$ by considering I_1, I_2 and $I_3 \cup I_4$ as a partition. Note also that a hyperplane arrangement has a structure of a multi-net in the sense of [FY] and $r \leq 4$, if the hypotheses (0.4-5) of Theorem 1(i) are satisfied, see Remark (3.3)(ii) below.

In this paper we also prove a non-combinatorial formula for the dimension of the non-unipotent monodromy part of the first Milnor cohomology generalizing [Di1], Ch.6, Th. 4.15. Let Σ be as in Proposition 1, and set

$$\Sigma(k) = \{y \in \Sigma \mid m_y k/d \in \mathbf{Z}\}.$$

For $y \in \Sigma$, let $\mathcal{I}_{\{y\}} \subset \mathcal{O}_Y$ be the reduced ideal of $\{y\} \subset Y$, and define

$$\mathcal{J}^{(k)} := \bigcap_{y \in \Sigma} \mathcal{I}_{\{y\}}^{\lceil m_y k/d \rceil - 2}, \quad \mathcal{J}^{(>k)} := \bigcap_{y \in \Sigma} \mathcal{I}_{\{y\}}^{\lfloor m_y k/d \rfloor - 1}.$$

Here $\lceil \alpha \rceil := \min\{k \in \mathbf{Z} \mid k \geq \alpha\}$, $\lfloor \alpha \rfloor := \max\{k \in \mathbf{Z} \mid k \leq \alpha\}$, and $\mathcal{I}_{\{y\}}^j = \mathcal{O}_Y$ for $j \leq 0$. Let $\mathbf{C}[X]_j$ denote the space of homogeneous polynomials of degree j . This is identified with $\Gamma(Y, \mathcal{O}_Y(j))$. Define

$$J_j^{(k)} := \Gamma(Y, \mathcal{O}_Y(j) \otimes_{\mathcal{O}_Y} \mathcal{J}^{(k)}) \subset \Gamma(Y, \mathcal{O}_Y(j)) = \mathbf{C}[X]_j.$$

Theorem 2. Assume $n = 3$. For $k \in [1, d-1]$, let $k' = d-k$ and $\lambda = \exp(2\pi i k/d)$. Then

$$\begin{aligned} \dim \operatorname{Gr}_F^0 H^1(F_f)_\lambda &= \dim \operatorname{Coker}(\rho^{(k)} : J_{k-3}^{(k)} \rightarrow \bigoplus_{y \in \Sigma(k)} \mathcal{J}_y^{(k)} / \mathcal{J}_y^{(>k)}) \\ &= \dim \operatorname{Coker}(\tilde{\rho}^{(k)} : \mathbf{C}[X]_{k-3} \rightarrow \bigoplus_{y \in \Sigma} \mathcal{O}_{Y, y} / \mathcal{J}_y^{(>k)}), \\ \dim \operatorname{Gr}_F^1 H^1(F_f)_\lambda &= \dim \operatorname{Coker}(\rho^{(k')} : J_{k'-3}^{(k')} \rightarrow \bigoplus_{y \in \Sigma(k)} \mathcal{J}_y^{(k')} / \mathcal{J}_y^{(>k')}) \\ &= \dim \operatorname{Coker}(\tilde{\rho}^{(k')} : \mathbf{C}[X]_{k'-3} \rightarrow \bigoplus_{y \in \Sigma} \mathcal{O}_{Y, y} / \mathcal{J}_y^{(>k')}), \end{aligned}$$

and $b_1(F_f)_\lambda = \dim \operatorname{Gr}_F^1 H^1(F_f)_\lambda + \dim \operatorname{Gr}_F^0 H^1(F_f)_\lambda$. Here we choose local trivializations of $\mathcal{O}_Y(k-3)$, $\mathcal{O}_Y(k'-3)$ to define the restriction morphisms $\tilde{\rho}^{(k)}$, $\tilde{\rho}^{(k')}$, etc. at $y \in \Sigma$.

Similar assertions in terms of superabundances (but without reference to the mixed Hodge structure) were obtained by A. Libgober, see [Li1], [Li2]. Note that for $\alpha = \frac{k}{d}$ and $0 < \varepsilon \ll 1/d$, we have

$$\mathcal{J}^{(k)} = \mathcal{J}(Y, (\alpha - \varepsilon)Z), \quad \mathcal{J}^{(>k)} = \mathcal{J}(Y, \alpha Z),$$

where $\mathcal{J}(Y, \alpha Z)$ is the multiplier ideal sheaf [La], see (2.3.4) below. Moreover, the target of the restriction morphism $\rho^{(k)}$ is identified with

$$\mathcal{G}(Y, \alpha Z) := \mathcal{J}(Y, (\alpha - \varepsilon)Z) / \mathcal{J}(Y, \alpha Z).$$

For simplicity assume $d/3 \in \mathbf{Z}$ and $m_y = 3$ ($\forall y \in \Sigma$). Set $k = 2d/3$, $k' = d/3$. Then the target of $\rho^{(k')}$ vanishes, and $\rho^{(k)}$ coincides with $\tilde{\rho}^{(k)}$ which is identified with the evaluation map (choosing points of $\mathbf{C}^3 \setminus \{0\}$ representing the points of Σ)

$$\bigoplus_{y \in \Sigma(k)} \operatorname{ev}_y^{k-3} : \mathbf{C}[X]_{k-3} \rightarrow \bigoplus_{y \in \Sigma(k)} \mathbf{C}_y.$$

So we get a partial generalization of [Di1], Ch.6, Th. 4.15 where $d = 9$. Note that $\operatorname{ev}_y^{k-3}$ can be defined and is surjective if $2d/3 < k < d$, although the surjectivity for $k = 2d/3$ does not hold in general. This follows from formulas for the spectrum, see [BS], Th. 3 and 5 (these are closely related to Mustařa's formula for the multiplier ideals [Mu], see also [Te]).

We would like to thank A. Libgober and S. Yuzvinsky for useful remarks, and the referee for valuable comments.

In Section 1 we recall theorems of Orlik, Solomon [OS] and Esnault, Schechtman, Viehweg [ESV] to show Proposition 1, and then prove Theorem 1. In Section 2 we prove Theorem 2 using the theory of multiplier ideals and Hodge theory. In Section 3 we give some examples and remarks.

1. Combinatorial description

1.1. Orlik-Solomon algebra. Let D be a central hyperplane arrangement in $X = \mathbf{C}^n$. Set $Y = \mathbf{P}^{n-1}$, and $U = Y \setminus Z$, where $Z = \mathbf{P}(D) := (D \setminus \{0\})/\mathbf{C}^*$. Let $\mathcal{S}(Z)$ denote the intersection lattice consisting of any intersections of the irreducible components Z_i of Z . For the definition of the Orlik-Solomon algebra, we allow the ambient space $\mathbf{P}^{n-1}$ as a member, but the empty set corresponding to $0 \in \mathbf{C}^n$ is excluded. (This is different from the definition in [BS], 1.1.) In particular, $\mathcal{S}(Z)$ is not a lattice in the strict sense, and is often called the “poset of intersections” in the literature. By [OS] there is an isomorphism of $\mathbf{C}$ -algebras

$$A_{\mathcal{S}(Z)}^\bullet \xrightarrow{\sim} H^\bullet(U, \mathbf{C}),$$

where $A_{\mathcal{S}(Z)}^\bullet$ is the quotient of the exterior algebra $\bigwedge^\bullet(\bigoplus_i \mathbf{C}e_i)$ by the ideal $\mathcal{I}_{\mathcal{S}(Z)}$. Here the e_i correspond to Z_i for $i = 1, \dots, d-1$ since we use the induced affine

arrangement on $\mathbf{C}^{n-1} = \mathbf{P}^{n-1} \setminus Z_d$, see [Br]. Moreover, $\mathcal{I}_{\mathcal{S}(Z)}$ is determined by the combinatorial data, see [OS].

1.2. Solution of Aomoto's conjecture. Let $\alpha_i \in \mathbf{C}$ for $i \in \{1, \dots, d\}$, and assume $\sum_{i=1}^d \alpha_i = 0$, and

$$(1.2.1) \quad \sum_{Z_i \supset V} \alpha_i \notin \mathbf{N} \setminus \{0\} \quad \text{for any dense edge } V \in \mathcal{S}(Z).$$

For the definition of “dense”, see [STV]. (In this paper the condition that V is dense may be replaced with $V \subset \Sigma$ since we assume essentially $n = 3$.) Note that (1.2.1) should be satisfied for $\mathcal{S}(Z)$, and not for $\mathcal{S}(Z)_{\langle d \rangle}$ in (1.3) below. In the notation of (1.1), set

$$\omega = \sum_{i=1}^{d-1} \alpha_i e_i \in \mathcal{A}_{\mathcal{S}(Z)}^1.$$

This defines a complex $(\mathcal{A}_{\mathcal{S}(Z)}^\bullet, \omega \wedge)$, called the Aomoto complex associated to ω . Note that e_i is identified with dg_i/g_i where g_i is a linear function with a constant term defining $Z_i \setminus Z_d \subset \mathbf{C}^{n-1}$. We also have a regular singular connection ∇^ω on $\mathcal{O}_U$ such that

$$\nabla^\omega g = dg + g\omega \quad \text{for } g \in \mathcal{O}_U.$$

Note that (1.2.1) is the condition on the distribution of the residues of the connection in [STV]. The main theorem of [ESV], [STV] assures that if (1.2.1) is satisfied, then we have a quasi-isomorphism

$$(1.2.2) \quad H_{\text{DR}}^\bullet(U, (\mathcal{O}_U, \nabla^\omega)) \xrightarrow{\sim} (\mathcal{A}_{\mathcal{S}(Z)}^\bullet, \omega \wedge).$$

This implies Proposition 1 in Introduction since the first condition of (0.2) coincides with (1.2.1) by setting

$$(1.2.3) \quad \alpha_i = \frac{k}{d} - 1 \text{ if } i \in I, \text{ and } \alpha_i = \frac{k}{d} \text{ otherwise.}$$

In case the second condition of (0.2) is satisfied, we replace k with $d - k$, and I with its complement, using the complex conjugation on the Milnor cohomology.

If condition (1.2.1) is not satisfied, then (1.2.2) may be false. However, we have always the following inequality (see [LY], Prop. 4.2)

$$(1.2.4) \quad \dim H_{\text{DR}}^j(U, (\mathcal{O}_U, \nabla^\omega)) \geq \dim H^j(\mathcal{A}_{\mathcal{S}(Z)}^\bullet, \omega \wedge).$$

So we get for any $a \in \mathbf{C}^*$

$$(1.2.5) \quad \dim H_{\text{DR}}^j(U, (\mathcal{O}_U, \nabla^{a\omega})) \geq \dim H^j(\mathcal{A}_{\mathcal{S}(Z)}^\bullet, a\omega \wedge) = \dim H^j(\mathcal{A}_{\mathcal{S}(Z)}^\bullet, \omega \wedge).$$

1.3. Generalized residues. Set

$$\mathcal{S}(Z)^{(k)} = \{V \in \mathcal{S}(Z) \mid \text{codim}_Y V = k\}.$$

Let $j_U : U \hookrightarrow Y$ denote the inclusion. Since it is an affine morphism, $\mathbf{R}(j_U)_* \mathbf{Q}_U[n-1]$ is a perverse sheaf [BBD] underlying naturally a mixed Hodge module [Sa1]. Let W be the weight filtration. By [BS], 1.7, there are constant variations of Hodge structures L_V of type $(0, 0)$ on V for $V \in \mathcal{S}(Z)$ such that we have for $i = 1, \dots, n-1$

$$(1.3.1) \quad \text{Gr}_{n-1+i}^W(\mathbf{R}(j_U)_* \mathbf{Q}_U[n-1]) = \bigoplus_{V \in \mathcal{S}(Z)^{(i)}} L_V(-i)[n-1-i],$$

where $\mathrm{Gr}_{n-1}^W(\mathbf{R}(j_U)_*\mathbf{Q}_U[n-1]) = \mathbf{Q}_Y[n-1]$). We may identify L_V with a Hodge structure since it is constant. Set

$$\mathcal{S}(Z)_{\langle d \rangle} = \{V \in \mathcal{S}(Z) \mid V \not\subset Z_d\}, \quad \mathcal{S}(Z)_{\langle d \rangle}^{(k)} = \mathcal{S}(Z)_{\langle d \rangle} \cap \mathcal{S}(Z)^{(k)}.$$

Then, restricting (1.3.1) to $Y \setminus Z_d = \mathbf{C}^{n-1}$, we get by [BS], 1.9

$$(1.3.2) \quad H^i(U, \mathbf{Q}) = \bigoplus_{V \in \mathcal{S}(Z)_{\langle d \rangle}^{(i)}} L_V(-i) \quad (i = 1, \dots, n-1).$$

This is compatible with the results of Brieskorn [Br] and Orlik, Solomon [OS], since $\dim L_V$ is given by the Möbius function in loc. cit. For each $V \in \mathcal{S}(Z)_{\langle d \rangle}^{(i)}$, we have the projection

$$\pi_V : H^i(U, \mathbf{Q}) \rightarrow L_V(-i).$$

This may be called the generalized residue along V .

In the notation of (1.2), set $e_i = dg_i/g_i$ for $1 \leq i < d$, and

$$e_{i_1, \dots, i_j} := e_{i_1} \wedge \dots \wedge e_{i_j} \in H^j(U, \mathbf{Q}).$$

This is compatible with the decomposition (1.3.2), i.e.

$$(1.3.3) \quad e_{i_1, \dots, i_j} \in L_V(-j) \subset H^j(U, \mathbf{Q}) \quad \text{with } V = Z_{i_1} \cap \dots \cap Z_{i_j}.$$

This means that its image by $\pi_{V'}$ for $V' \neq V$ vanishes. The assertion is shown by taking a sub-arrangement $Z' \subset Z$ consisting of $Z_{i_1}, \dots, Z_{i_j}, Z_d$, and using the compatibility of the exterior product with the restriction morphism by the inclusion $U \hookrightarrow U' := \mathbf{P}^{n-1} \setminus Z'$, since the construction of L_V is functorial for Z . Indeed, taking the graded pieces of the canonical morphism

$$\mathbf{R}(j_{U'})_* \mathbf{Q}_{U'}[n-1] \rightarrow \mathbf{R}(j_U)_* \mathbf{Q}_U[n-1],$$

the obtained morphism is compatible with the direct sum decomposition in (1.3.1) (since the direct factors in (1.3.1) are simple perverse sheaves with different supports). Note that $H^j(U', \mathbf{Q}) = \mathbf{Q}$ where j is as above, and $L_V = \mathbf{Q}$ if Z is a divisor with normal crossings at the generic point of V .

The following lemma is well known to the specialists, see [LY], Lemma 3.1 (and also [Fa], [Li2], [Yu1]) where the situation is localized at V using the fact that the relations of the Orlik-Solomon algebra are of the form $\partial(e_J)$ for certain J and are compatible with the decomposition by V . We note here a short proof for the convenience of the reader.

Set $I_V = \{i \mid Z_i \supset V\}$, and $\alpha_V = \sum_{i \in I_V} \alpha_i$, where $\omega = \sum_{i=1}^{d-1} \alpha_i e_i$ as above.

Lemma 1.4. *Let $\eta = \sum_{i=1}^{d-1} \beta_i e_i$ with $\beta_i \in \mathbf{C}$. For $V \in \mathcal{S}(Z)_{\langle d \rangle}^{(2)}$ we have*

$$(1.4.1) \quad \alpha_V \beta_i = \beta_V \alpha_i \quad (\forall i \in I_V) \quad \text{if } \pi_V(\omega \wedge \eta) = 0.$$

Proof. For $i, j, k \in I_V$, it is easy to show the relation (see e.g. [OS])

$$(1.4.2) \quad e_{i,j} + e_{j,k} = e_{i,k}.$$

In the case $\mathrm{codim}_Y V = 2$, we have $\dim L_V = |I_V| - 1$ by the definition of L_V in [BS], 1.7. (This is related to the theory of Möbius function [OS]). Hence L_V has a basis consisting of $e_{i,k}$ ($i \neq k$) for any fixed $k \in I_V$.

By hypothesis we have for any $k \in I_V$ the vanishing of

$$\sum_{i,j \in I_V} \alpha_i \beta_j e_{i,j} = \sum_{i,j \in I_V} \alpha_i \beta_j (e_{i,k} - e_{j,k}) = \sum_{i \in I_V} (\alpha_i \beta_V - \beta_i \alpha_V) e_{i,k}.$$

This implies $\alpha_V \beta_i = \beta_V \alpha_i$ for any $i \in I_V \setminus \{k\}$. However, k can vary in I_V . So the assertion follows.

1.5. Kernel of the differential $\omega \wedge$. The subject of this subsection has been studied very well in [Fa], [LY], [FY]. Assume $n = 3$. Set $J' = \{1, \dots, d-1\}$, and let

$$\omega = \sum_{i=1}^{d-1} \alpha_i e_i \quad \text{with } \alpha_i \in \mathbf{C}^*.$$

With the notation of (1.4), set $\alpha_y = \alpha_V := \sum_{i \in I_V} \alpha_i$ if $V = \{y\}$. Let $Z' = Z \setminus Z_d$, and

$$\Sigma_{\langle d \rangle} = \{y \in Z' \mid \text{mult}_y Z' \geq 3\}, \quad \Sigma_{\langle d \rangle}^\alpha = \{y \in \Sigma_{\langle d \rangle} \mid \alpha_y = 0\}.$$

Let Z'^α be the proper transform of Z' by the blow-up of $Y' := Y \setminus Z_d$ along $\Sigma_{\langle d \rangle}^\alpha$. We say that $I \subset J'$ is α -connected, if $\bigcup_{j \in I} Z'_j$ is the image of a connected subvariety of Z'^α , where $Z'_1, \dots, Z'_{d-1}$ are the irreducible components of Z' . Note that the set of α -connected components is a “neighborly partition” in [Fa], [LY]. Let $J'_1, \dots, J'_{r'}$ be the α -connected components of J' .

Let $\eta = \sum_{i=1}^{d-1} \beta_i e_i$ with $\beta_i \in \mathbf{C}$, and assume

$$\omega \wedge \eta = 0.$$

By Lemma (1.4), there are $c_k \in \mathbf{C}$ ($k = 1, \dots, r'$) such that

$$(1.5.1) \quad \beta_i = c_k \alpha_i \quad \text{for } i \in J'_k.$$

So we assume $r' \geq 2$ since $H^1(\mathcal{A}_{S(Z)}^\bullet, \omega \wedge) = 0$ otherwise. In this case there are intersections $Z'_i \cap Z'_j = \{y\}$ such that i, j belong to different α -connected components and $y \in \Sigma_{\langle d \rangle}^\alpha$. So $\alpha_y = 0$, and Lemma (1.4) implies a further condition

$$(1.5.2) \quad \beta_y := \sum_{i \in I_y} \beta_i = 0 \quad (y \in \Sigma_{\langle d \rangle}^\alpha).$$

However, the relation between these conditions for different $y \in \Sigma_{\langle d \rangle}^\alpha$ is quite non-trivial, see [Fa], [FY]. Since the image of $\omega \wedge$ in $\mathcal{A}_{S(Z)}^1$ is 1-dimensional, we get at least

$$(1.5.3) \quad \dim H^1(\mathcal{A}_{S(Z)}^\bullet, \omega \wedge) \leq r' - 2.$$

1.6. Proof of Theorem 1. Define the connection ∇^ω as in (1.2) setting $I = I_{j_0}$ for the j_0 in (0.5), where $k = d/m$ and the α_i are defined as in (1.2.3) (although (1.2.1) is not necessarily satisfied). Then $\alpha_y = 0$ ($y \in \Sigma_{\langle d \rangle}^\phi$) by the last condition of (0.5), and we get

$$\Sigma_{\langle d \rangle}^\alpha = \Sigma_{\langle d \rangle}^\phi,$$

since the inclusion $\subset$ follows from the constantness of α_i on each I_j . Note that I_j is not necessary α -connected in the sense of (1.5). However, we may consider the case

$$\beta_i = c_{\phi(i)} \quad (i = 1, \dots, d-1),$$

where $c_j \in \mathbf{C}$ ($j = 1, \dots, r$). Then the condition given by (1.5.2) is written as

$$\sum_{j=1}^r m_{j,y} c_j = 0 \quad (y \in \Sigma_{\langle d \rangle}^\alpha),$$

and it is independent of $y \in \Sigma_{\langle d \rangle}^\alpha$ by the last condition of (0.4). We get thus

$$\dim H^1(\mathcal{A}_{S(Z)}^\bullet, \omega \wedge) \geq r - 2,$$

since $\dim \omega \wedge \mathcal{A}_{S(Z)}^0 = 1$. (Here $\Sigma_{\langle d \rangle}^\phi$ may be empty.) So the desired inequality for $\lambda = \exp(2\pi i a/m)$ ($a = 1, \dots, m$) follows from (1.2.5).

If (0.6) is satisfied, then (0.4) and (0.5) are also satisfied. In this case we have $\Sigma_{\langle d \rangle}^\phi \neq \emptyset$ since $|I_j| = d/r \geq 2$. Since the Milnor monodromy is defined over $\mathbf{Q}$, it is enough to consider the case $\lambda = \exp(2\pi i/m)$ using the Galois group of $\overline{\mathbf{Q}}/\mathbf{Q}$ which acts transitively on the primitive m -th roots of unity. We define α_i and ω as above where (0.2) is satisfied for $I = I_{j_0}$. In this case each I_j is α -connected, since $Z'_i \cap Z'_{i'}$ for $i, i' \in I_j$ cannot belong to $\Sigma_{\langle d \rangle}^\alpha$ by the condition $m_{j,y} = 1$ for $y \in \Sigma^\phi$. So we get

$$\dim H^1(\mathcal{A}_{S(Z)}^\bullet, \omega \wedge) = m - 2,$$

and the assertion follows from Proposition 1. This finishes the proof of Theorem 1.

2. Non-combinatorial description

2.1. Mixed Hodge complexes. Set $\Sigma = \{y \in Z \mid \text{mult}_y Z \geq 3\}$ as in Introduction. Let $\pi : \tilde{Y} \rightarrow Y$ be the blow-up of $Y = \mathbf{P}^2$ along Σ . Set $\tilde{Z} = \pi^{-1}(Z)$. Let $L^{(k)}$ be the local system on U calculating $H^\bullet(F_f, \mathbf{C})_\lambda$ for $\lambda = \exp(2\pi i k/d)$ as in Introduction. Let $\mathcal{L}^{(k)}$ be the Deligne extensions over $\tilde{Y}$ such that the eigenvalues of the residue of the connection are contained in $[0, 1)$, see [D1].

It is well-known (see e.g. [Es], [Ti]) that the Hodge filtration F on the Milnor cohomology $H^\bullet(F_f, \mathbf{C})_\lambda = H^\bullet(U, L^{(k)})$ is given by the logarithmic de Rham complex whose j -th component is

$$\text{DR}_{\log}^j \mathcal{L}^{(k)} := \Omega_{\tilde{Y}}^j(\log \tilde{Z}) \otimes_{\mathcal{O}} \mathcal{L}^{(k)},$$

where the Hodge filtration F^p is induced by the truncation $\sigma_{\geq p}$ in [D2], 1.4.7. By the strict compatibility of the Hodge filtration F , we get

$$(2.1.1) \quad \text{Gr}_F^p H^{p+q}(F_f, \mathbf{C})_\lambda = H^q(\tilde{Y}, \Omega_{\tilde{Y}}^p(\log \tilde{Z}) \otimes_{\mathcal{O}} \mathcal{L}^{(k)}).$$

It is also well-known (see e.g. [BS], 1.4) that

$$(2.1.2) \quad \mathcal{L}^{(k)} = \mathcal{O}_{\tilde{Y}}((-k)\tilde{H} + \sum_{y \in \Sigma} \lfloor m_y k/d \rfloor E_y),$$

where $\lfloor \alpha \rfloor := \max\{k \in \mathbf{Z} \mid k \leq \alpha\}$, and $\tilde{H}$ is the pull-back of a general hyperplane $H \subset Y$.

2.2. Weight filtration. Let $\tilde{j} : U \rightarrow \tilde{Y}$ denote the inclusion. The perverse sheaf $\mathbf{R}\tilde{j}_* L^{(k)}[2]$ has the weight filtration W such that

$$(2.2.1) \quad \text{Gr}_2^W(\mathbf{R}\tilde{j}_* L^{(k)}[2]) = \text{IC}_Y L^{(k)} = (\tilde{j}_* L^{(k)})[2],$$

where the middle term is the intersection complex with coefficients in the local system $L^{(k)}$, see [BBD], [GM]. Here the local monodromy of $L^{(k)}$ is trivial only around the exceptional divisors E_y for $y \in \Sigma(k)$, and these are smooth and disjoint. This implies

$$(2.2.2) \quad \mathrm{Gr}_k^W(\mathbf{R}\tilde{j}_*L^{(k)}[2]) = 0 \quad \text{for } k \neq 2, 3.$$

Let $\tilde{Z}'$ be the proper transform of Z , and set $E'_y = E_y \setminus \tilde{Z}'$ with the inclusion $j_y : E'_y \rightarrow E_y$. For $y \in \Sigma(k)$, $L^{(k)}$ can be extended over $U \cup E'_y$, since the local monodromy around E'_y is trivial. Let $L_{E'_y}^{(k)}$ be its restriction over E'_y . Then

$$(2.2.3) \quad \mathrm{Gr}_3^W(\mathbf{R}\tilde{j}_*L^{(k)}[2]) = \bigoplus_{y \in \Sigma(k)} ((j_y)_*L_{E'_y}^{(k)})[1],$$

2.3. Multiplier ideals. Let Y be a smooth complex algebraic variety, and Z be a divisor on it. Let $\pi : \tilde{Y} \rightarrow Y$ be an embedded resolution of Z . Set $\tilde{Z} := \pi^*Z = \sum_i m_i \tilde{Z}_i$. The following is well-known (see e.g. [La]).

For $\alpha \in \mathbf{Q}_{>0}$, the multiplier ideal sheaves $\mathcal{J}(Y, \alpha Z)$ are defined by

$$(2.3.1) \quad \mathcal{J}(Y, \alpha Z) = \pi_*(\omega_{\tilde{Y}/Y} \otimes_{\mathcal{O}} \mathcal{O}_{\tilde{Y}}(-\sum_i \lfloor \alpha m_i \rfloor \tilde{Z}_i)),$$

and we have the local vanishing theorem (see loc. cit. 9.4.1)

$$(2.3.2) \quad R^i \pi_*(\omega_{\tilde{Y}/Y} \otimes_{\mathcal{O}} \mathcal{O}_{\tilde{Y}}(-\sum_i \lfloor \alpha m_i \rfloor \tilde{Z}_i)) = 0 \quad (i > 0).$$

Moreover, if Y is proper and Z' is another divisor on Y such that $Z' - \alpha Z$ is nef and big, then we have the vanishing theorem of Nadel (see loc. cit. 9.4.8)

$$(2.3.3) \quad H^i(Y, \omega_Y \otimes_{\mathcal{O}} \mathcal{O}_{\tilde{Y}}(Z') \otimes \mathcal{J}(Y, \alpha Z)) = 0 \quad (i > 0).$$

If Z is a projective hyperplane arrangement in $Y = \mathbf{P}^2$ with reduced structure, let $\mathcal{I}_{\{y\}}$ be the reduced ideal sheaf of $\{y\} \subset Y$. It is well-known that

$$(2.3.4) \quad \mathcal{J}(Y, \alpha Z) = \bigcap_{y \in \Sigma} \mathcal{I}_{\{y\}}^{\lfloor \alpha m_y \rfloor - 1} \quad \text{for } \alpha > 0.$$

This is a special case of Mustař's formula [Mu].

Theorem 2.4. *For $\lambda = \exp(2\pi i k/d)$, we have a canonical isomorphism*

$$(2.4.1) \quad \mathrm{Gr}_F^0 H^1(F_f, \mathbf{C})_\lambda = H^1(Y, \mathcal{O}_Y(k-3) \otimes_{\mathcal{O}} \mathcal{J}(\frac{k}{d}Z))^\vee.$$

Proof. By (2.1.1–2) together with Serre duality, we have

$$\begin{aligned} \mathrm{Gr}_F^0 H^1(F_f, \mathbf{C})_\lambda &= H^1(\tilde{Y}, \mathcal{O}_{\tilde{Y}}((-k)\tilde{H} + \sum_{y \in \Sigma} \lfloor m_y k/d \rfloor E_y)) \\ &= H^1(\tilde{Y}, \mathcal{O}_{\tilde{Y}}((k-3)\tilde{H} + \sum_{y \in \Sigma} (1 - \lfloor m_y k/d \rfloor) E_y))^\vee. \end{aligned}$$

Here $\omega_{\tilde{Y}/Y} = \mathcal{O}_{\tilde{Y}}(\sum_{y \in \Sigma} E_y)$, and hence $\Omega_{\tilde{Y}}^2 = \mathcal{O}_{\tilde{Y}}(-3\tilde{H} + \sum_{y \in \Sigma} E_y)$. So the assertion follows from (2.3.1–2).

2.5. Proof of Theorem 2. Set first $\alpha = \frac{k}{d}$, and $\alpha' = \alpha - \varepsilon$ with $0 < \varepsilon \ll 1/d$. With the notation of Introduction, we have the short exact sequence

$$(2.3.1) \quad 0 \rightarrow \mathcal{J}(Y, \alpha Z) \rightarrow \mathcal{J}(Y, \alpha' Z) \rightarrow \mathcal{G}(Y, \alpha Z) \rightarrow 0.$$

Since $\mathcal{O}_Y(Z) = \mathcal{O}_Y(d)$ and $\alpha'd < k$, we have by (2.3.3)

$$(2.5.2) \quad H^1(Y, \mathcal{O}_Y(k-3) \otimes \mathcal{J}(Y, \alpha'Z)) = 0.$$

Then, after taking the tensor product of (2.3.1) with $\mathcal{O}_Y(k-3)$, we get the associated long exact sequence

$$H^0(Y, \mathcal{J}(\alpha'Z)(k-3)) \xrightarrow{\gamma} H^0(Y, \mathcal{G}(\alpha Z)(k-3)) \rightarrow H^1(Y, \mathcal{J}(\alpha Z)(k-3)) \rightarrow 0,$$

where $\mathcal{J}(\alpha Z)(k-3) := \mathcal{J}(Y, \alpha Z) \otimes \mathcal{O}_Y(k-3)$ and similarly for $\mathcal{G}(\alpha Z)(k-3)$. Moreover, γ is identified with $\rho^{(k)}$ as is explained after Theorem 2. So the first equality in Theorem 2 follows from Theorem (2.4).

For the proof of the second equality, we show, in the above notation, that the first equality holds with the right-hand side replaced by the dimension of

$$\text{Coker}(H^0(Y, \mathcal{J}(\beta Z)(k-3)) \rightarrow H^0(Y, \mathcal{J}(Y, \beta Z)/\mathcal{J}(Y, \alpha Z))),$$

by decreasing induction on $0 < \beta < \alpha = \frac{k}{d}$. If $\beta = \alpha'$, this is the first equality. Assume the assertion holds for β , and set $\beta' = \beta - \varepsilon$. We have a long exact sequence

$$0 \rightarrow H^0(Y, \mathcal{J}(\beta Z)(k-3)) \rightarrow H^0(Y, \mathcal{J}(\beta' Z)(k-3)) \xrightarrow{\gamma} H^0(Y, \mathcal{G}(\beta Z)(k-3)) \rightarrow,$$

and the morphism γ is surjective by (2.5.2) with α' replaced by β . So the assertion holds also for β' using the snake lemma since the support of $\mathcal{J}(Y, \beta' Z)/\mathcal{J}(Y, \alpha Z)$ is contained in a 0-dimensional subset Σ . Thus the assertion for $\text{Gr}_F^0 H^1(F_f)_\lambda$ is proved.

For $\text{Gr}_F^1 H^1(F_f)_\lambda$, we have by (2.2.2-3)

$$(2.5.3) \quad H^1(F_f)_\lambda \oplus H^1(F_f)_{\bar{\lambda}} \text{ is pure of weight 1.}$$

Indeed, using the weight spectral sequence, it is enough to show that the local system $L_{E'_y}^{(k)}$ on E'_y has no nontrivial global sections, i.e. the local monodromies of $L_{E'_y}^{(k)}$ around $E_y \cap \tilde{Z}'$ are nontrivial. But this is clear by the construction of $L_{E'_y}^{(k)}$ before (2.2.3). So (2.5.3) follows. (See [DP] for another proof of (2.5.3).)

Using the complex conjugation, we then get

$$\dim \text{Gr}_F^1 H^1(F_f)_\lambda = \dim \text{Gr}_F^0 H^1(F_f)_{\bar{\lambda}},$$

and the assertion for $\text{Gr}_F^1 H^1(F_f)_\lambda$ follows. This finishes the proof of Theorem 2.

3. Examples and Remarks

Examples 3.1. The following examples are studied in [CS], [Di1], etc.

(i) Let $n = 3$, $d = 6$, and

$$f = xyz(x-y)(x-z)(y-z).$$

This is the simplest example with $b_1(F_f)_\lambda \neq 0$ ($\lambda \neq 1$). Here $\lambda = \exp(2\pi i/3)$. In this case, (0.2) for $k = 2$ and (0.6) for $r = m = 3$ are both satisfied.

(ii) Let $n = 3$, $d = 9$, and

$$f = xyz(x-y)(y-z)(x-y-z)(2x+y+z)(2x+y-z)(2x-5y+z).$$

This is the second simplest example with $b_1(F_f)_\lambda \neq 0$ ($\lambda \neq 1$). Here $\lambda = \exp(2\pi i/3)$. In this case, (0.2) for $k = 3$ and (0.6) for $r = m = 3$ are both satisfied. This arrangement is dual to the Pappus configuration.

(iii) Let $n = 3$, $d = 9$, and

$$f = xyz(x+y)(y+z)(x+3z)(x+2y+z)(x+2y+3z)(2x+3y+3z).$$

Then $b_1(F_f)_\lambda = 0$ for $\lambda \neq 1$. In this case neither (0.2) for $k = 3$ nor (0.6) for $r = m = 3$ is satisfied. So we need Theorem 2 or [Di1], Ch.6, Th. 4.15 to calculate $b_1(F_f)_\lambda$ for $\lambda = \exp(\pm 2\pi i/3)$, see also [CS]. The referee has pointed out that (1.2.2) holds for this example even though (0.2) is not satisfied.

Remarks 3.2. (i) According to A. Libgober, there is an example with $n = 3$, $d = 9$, $|\Sigma| = 12$, and $Z := \mathbf{P}(D)$ has no ordinary double point. It is the dual of the nine inflection points of a smooth cubic curve E in the dual projective space $\mathbf{P}^2$, see [Li2], p. 243, Ex. 2. This is shown by choosing an inflection point as the origin O of the group law so that there is a line passing through three points P_1, P_2, P_3 on E if and only if

$$P_1 + P_2 + P_3 = O.$$

In this case conditions (0.4–5) are satisfied so that $b_1(F_f)_\lambda \neq 0$ for $\lambda = \exp(\pm 2\pi i/3)$ although (0.2) cannot to be satisfied. The referee has pointed out that the inequality (1.2.4) is strict in this example.

If the cubic curve is given by $u^3 + v^3 + w^3 = 0$, then

$$f = (x^3 - y^3)(x^3 - z^3)(y^3 - z^3),$$

and setting $\theta = \exp(\pm 2\pi i/3)$, we have

$$\Sigma = \{(\theta^i : \theta^j : 1) \mid i, j = 0, 1, 2\} \cup \{(1 : 0 : 0), (0 : 1 : 0), (0 : 0 : 1)\} \subset \mathbf{P}^2.$$

In this case the evaluation map $\bigoplus_{y \in \Sigma} \text{ev}_y^3$ explained after Theorem 2 is injective so that $b_1(F_f)_\lambda = 2$ for $\lambda = \exp(\pm 2\pi i/3)$ using [Di1], Ch.6, Th. 4.15 or Theorem 2 in Introduction. (This follows from the assertion that $a = b = c = 0$ if $a\theta^{2i} + b\theta^i + c = 0$ for $i = 0, 1, 2$ where $a, b, c \in \mathbf{C}$. We have a more geometric proof using the fact that any Z_i contains 4 points of Σ so that any cubic polynomial vanishing on Σ has to vanish on any Z_i .)

(ii) The argument in Remark (i) can be used to construct further examples with $b_1(F_f)_\lambda = 1$ for $\lambda = \exp(\pm 2\pi i/3)$. Indeed, take a finite subgroup G of E together with three points P_1, P_2, P_3 such that $P_1 + P_2 + P_3 = O$ and $P_i - P_j \notin G$ for any $i \neq j$, see [Yu2]. Consider the dual line arrangement associated to $P_i + Q$ for $i = 1, 2, 3$ and $Q \in G$ where $d = 3|G|$ and $\text{mult}_y Z \leq 3$ for any $y \in \Sigma$ (since the degree of the curve is 3). Then (0.6) for $r = m = 3$ is satisfied if furthermore $3P_i \notin G$ for some i (since the last condition implies that the second condition of (0.3) holds). This gives examples with the same combinatorial data as Examples (3.1)(i) and (ii). Here “same combinatorial data” means that there is an isomorphism between the intersection lattices defined by the intersections of their irreducible components. If we set $P_1 = 0$ with $P_2 = -P_3$ generic and if $|G| = 3$, then we get an example where

$d = 9$, $|\Sigma| = 10$ and $b_1(F_f)_\lambda = 1$ for $\lambda = \exp(\pm 2\pi i/3)$ by Theorem 1 (ii). This example is the specialization of the Pappus arrangement in Example (3.1)(ii), see [Fa].

(iii) As for Example (3.1)(iii), a line arrangement with the same combinatorial data can be constructed as follows. Choose a finite subgroup $G = \mathbf{Z}/27\mathbf{Z}$ in an elliptic curve, and then take the subset J of G consisting of $a \in G$ with $a - 1 \in 3G$. The irreducible components of D defined by the linear factors of f in Example (3.1)(iii) correspond, for example, to

$$7, 1, 4, 19, 22, 16, 13, 10, 25 \in \mathbf{Z}/27\mathbf{Z},$$

respecting the order of the factors of f (and this is confirmed by the referee using Mathematica). It means that we have $a + b + c = 0$ in G if and only if the corresponding three lines meet at a point. (We can associate $a' := (a-1)/3 \in \mathbf{Z}/9\mathbf{Z}$ to $a \in J$. Then the above condition is equivalent to that $a' + b' + c' = -1$ in $\mathbf{Z}/9\mathbf{Z}$, and the latter may be easier to handle.)

(iv) In the case $\text{mult}_y Z \leq 3$ ($\forall y \in \Sigma$), it is sometimes possible to construct a finite subset of an elliptic curve defining a line arrangement which is combinatorially equivalent to a given line arrangement Z as follows. Let M be a matrix of size (q, d) (where $q = |\Sigma|$) such that if $y \in \Sigma$ is the intersection of three lines $Z_{i_1}, Z_{i_2}, Z_{i_3}$, then it corresponds to a row vector v_y of M such that

$$v_{y,i} = \begin{cases} 1 & \text{if } i \in \{i_1, i_2, i_3\}, \\ 0 & \text{if } i \notin \{i_1, i_2, i_3\}. \end{cases}$$

Consider the equation

$$Mx = 0.$$

If it has a nontrivial solution x in a finite abelian group G generated by two elements, and if the components x_i of x are all different from each other, then the x_i may define the desired line arrangement after embedding G into an elliptic curve. Here one problem is that new triple points may appear, i.e. there may exist distinct elements $x_{i_1}, x_{i_2}, x_{i_3}$ whose sum is O and which do not correspond to any row vector of M . (In the case of Example (iii) the size of M is 9×9 , and its determinant is 27. So we can solve the equation mod 27. We can also count the number of the triple points, which is 9.)

Remarks 3.3. (i) If $m_{j,y} = 1$ ($\forall y \in \Sigma^\phi$) in the notation of Theorem 1, then $|I_j|$ is independent of j as remarked after Theorem 1, and hence Z is an $(m, d/m)$ -net. So it is associated to a pencil on $\mathbf{P}^2$ by the Nullstellensatz, see [Yu2], Lemma 3.1. Then Theorem 1 (i) follows as is shown in [DP], Th. 3.1 (i) in a more general case. Indeed, the existence of a pencil implies that there is a surjective morphism of algebraic varieties

$$h : U \rightarrow S := \mathbf{P}^1 \setminus \{m \text{ points}\},$$

and moreover the local system $L^{(k)}$ on U is the pull-back of a local system $L_S^{(k)}$ on S . Since $\dim H^1(S, L_S^{(k)}) = m - 2$, Theorem 1 (i) then follows from the injectivity

of the pull-back

$$H^1(S, L_S^{(k)}) \rightarrow H^1(U, L^{(k)}).$$

Note that the condition $m_{j,y} = 1$ ($\forall y \in \Sigma^\phi$) implies that there is a natural compactification $\bar{h} : \bar{U} \rightarrow S$ of $h : U \rightarrow S$ such that $\bar{U} \setminus U = \Sigma^\phi \times S$. Hence the base change holds for $h : U \rightarrow S$ and $\{s\} \hookrightarrow S$, and the Leray spectral sequence for h degenerates at E_2 since $E_2^{p,q} = 0$ unless $q = 0, 1$.

(ii) By [DPS], [FY], [Yu3], we have $r \leq 4$ if conditions (0.4–5) are satisfied in Theorem 1 (i). Indeed, if E denotes the irreducible component of the resonance variety $R_1(Z)$ (see [Fa]) containing ω in the proof of Theorem 1, then we have by [DPS], Prop. 7.8(i)

$$\dim E = H^1(\mathcal{A}_{S(D)}^\bullet, \omega \wedge) + 1 \geq r - 1,$$

where the last inequality follows from the proof of Theorem 1(i). Moreover, there is a correspondence between the components E and the pencils, see [FY] (and also [Di3]). Then we get the inequality $\dim E \leq 3$ by using [Yu3]. So the desired inequality follows. This argument also shows that a hyperplane arrangement has a structure of a multi-net in the sense of [FY] if the hypotheses (0.4) and (0.5) of Theorem 1(i) are satisfied.

(iii) For the moment only one example is known where the hypotheses of Theorem 1 are satisfied with $m = 4$. This is induced by the Hesse pencil (see [FY], Ex. 3.5 and [St1])

$$s_0(x^3 + y^3 + z^3) - s_1xyz \quad (s_0, s_1 \in \mathbf{C}).$$

Calculating the logarithmic differential of $(x^3 + y^3 + 1)/xy$, the singular members of the pencil are given by

$$s_1/s_0 = 3, \quad 3\theta, \quad 3\bar{\theta}, \quad \infty,$$

where $\theta = \exp(\pm 2\pi i/3)$. So the line arrangement is defined by

$$f = xyz \prod_{j=0}^2 (x^3 + y^3 + z^3 - 3\theta^j xyz) = xyz \prod_{i,j=0}^2 (\theta^i x + \theta^j y + z).$$

In this case $d = 12$, and $|\Sigma| = 9$. More precisely

$$\begin{aligned} \Sigma &= \{x^3 + y^3 + z^3 = 0\} \cap \{xyz = 0\} \\ &= \{(-\theta^i : 1 : 0), (-\theta^i : 0 : 1), (0 : -\theta^i : 1) \mid i = 0, 1, 2\} \subset \mathbf{P}^2. \end{aligned}$$

Then condition (0.6) is satisfied for $m = r = 4$ where ϕ corresponds to the first factorization of f . So we get $b_1(F_f)_{-1} \geq 2$ by Theorem 1 (i), and $b_1(F_f)_{\pm i} = 2$ by Theorem 1 (ii) (see also [DP]). For $\lambda = -1$, we can calculate $b_1(F_f)_{-1}$ by using Theorem 2 where $d = 12$, $k = k' = 6$, and $m_y = 4$ for $y \in \Sigma$. In this case, $\dim \mathbf{C}[X]_3 = 10$, and $\rho^{(6)} = \tilde{\rho}^{(6)}$ is identified with the evaluation map at Σ . Its kernel is generated by $x^3 + y^3 + z^3$ and xyz , and its cokernel is 1-dimensional. So we get $b_1(F_f)_{-1} = 2$. It is also possible to calculate $b_1(F_f)_{\pm i}$ by using Theorem 2.

Remarks 3.4. (i) Let f be a holomorphic function on a complex manifold X . Let $\psi_{f,\lambda} \mathbf{C}_X$ denote the λ -eigenspace of the nearby cycle functor $\psi_f \mathbf{C}_X$. It is well-known that $\psi_{f,\lambda} \mathbf{C}_X$ is a perverse sheaf up to a shift of complex, and its stalk at $y \in f^{-1}(0)$

gives $H^\bullet(F_{f,y}, \mathbf{C})_\lambda$ where $F_{f,y}$ denotes the Milnor fiber of f around y . These imply that $H^j(F_{f,y}, \mathbf{C})_\lambda = 0$ for $j \neq \dim X - 1$ if $H^j(F_{f,y'}, \mathbf{C})_\lambda = 0$ for any $j \in \mathbf{Z}$ and any $y' \neq y$ sufficiently near y .

(ii) In the case of a hyperplane arrangement, an assertion stronger than (i) is known as follows. We have $b_1(F_f)_\lambda = 0$ unless each Z_i contains $y \in \Sigma$ with $\lambda^{m_y} = 1$ (see [Li3], Th. 3.1 or [Di2], Th. 6.4.13), where we may assume $n = 3$ by (0.1). Indeed, if there is Z_i containing no point y of Σ with $\lambda^{m_y} = 1$, then letting $j : U \hookrightarrow Y$, $j_i : U_i := Y \setminus Z_i \hookrightarrow Y$ denote the inclusions, we have

$$\mathbf{R}j_*L^{(k)} = (j_i)_!j_i^*(\mathbf{R}j_*L^{(k)}),$$

using the blow-up along Σ , where $\lambda = \exp(2\pi i k/d)$. Then the assertion follows from Artin's theorem on the generalization of the weak Lefschetz theorem for perverse sheaves [BBD].
